

SETTING UP AND USING A FIREWALL ON WINDOWS/LINUX

TASK 4: GUIDELINES FOR SETTING UP AND USING A FIREWALL ON WINDOWS/LINUX

Objective:

- Configure and test basic firewall rules to allow or block network traffic.

Tools:

- Windows Firewall
- UFW (Uncomplicated Firewall) on Linux

Deliverables:

- Screenshot or configuration file showing applied firewall rules.
- Documentation of commands or GUI steps used.

Mini Guide / Steps:

- Open the firewall configuration tool:
 - o Windows: Windows Firewall
 - o Linux: Terminal for UFW
- List current firewall rules.
- Add a rule to block inbound traffic on a specific port (e.g., port 23 for Telnet).
- Test the rule by attempting to connect to that port locally or remotely.
- Add a rule to allow SSH (port 22) if using Linux.
- Remove the test block rule to restore the original state.
- Document all commands or GUI steps used.
- Summarize how the firewall filters and controls network traffic.

Interview Questions:

- What is a firewall?
- What is the difference between stateful and stateless firewalls?
- What are inbound and outbound rules?
- How does UFW simplify firewall management?
- Why is it important to block port 23? (Telnet)
- What are common firewall configuration mistakes?
- How does a firewall improve network security?
- What is NAT (Network Address Translation) in firewalls?

Key Concepts:

- Firewall configuration
- Network traffic filtering
- Ports and services
- UFW (Linux)
- Windows Firewall
